

Credit Card Transactions

Data Analysis Case Study using MS SQL Server

**Note: By using stored procedures one could provide fast, secure, reusable analytics with automatic audit logging for production-ready performance.*

Stored Procedure based Analysis

1. Write a stored procedure that accepts a city name as input and returns the top 10 transactions (all columns) for that city ordered by transaction_date descending.
2. Write a stored procedure that takes a card_type and a year as parameters and returns the total spend per month for that card_type in that year.
3. Write a stored procedure that accepts a minimum and maximum amount range and returns all transactions where the amount falls within that range, along with total count and total spend as output parameters.
4. Write a stored procedure that takes an expense type as input and returns, for each city, the percentage contribution of that city's spends for that expense type to the total spend of that expense type.
